Target audience: Clinicians who perform neurovascular assessments on paediatric patients

Description: A guideline for an orthopaedic neurovascular assessment of babies, children and young people

---

Keywords: Limb observations, neurovascular observations, extremity, assessment

Document registration number: JHCH 10.4

Replaces existing document? No

Related Legislation, Australian Standard, NSW Ministry of Health Policy Directive or Guideline, National Safety and Quality Health Service Standard (NSQHSS) and/or other, HNE Health Document, Professional Guideline, Code of Practice or Ethics:
- NSW Ministry of Health Infection Control Policy PD2007 036
- NSW Ministry of Health Hand Hygiene Policy PD 2010 058
- NSW Health Policy Directive 2014_036 Clinical Procedure Safety

Prerequisites (if required): Nil

Local Guideline note: This document reflects what is currently regarded as safe and appropriate practice. The guideline section does not replace the need for the application of clinical judgment in respect to each individual patient but the procedure/s require mandatory compliance. If staff believe that the procedure/s should not apply in a particular clinical situation they must seek advice from their unit manager/delegate and document the variance in the patients health record.

Position responsible for the Local Guideline and authorised by: Pat Marks. General Manager / Director of Nursing CYPFS

Contact person: Kim Tomasic, Clinical Nurse Consultant, Paediatric Orthopaedics

Version 1  May 2016  Page 3
hand or foot function

- Check for sensation
- Check weight of traction does not exceed 10% of child’s weight
- Check for signs of compression or swelling
- Instigate clinical review within 30 minutes
- Increase frequency of neurovascular assessment according to recommendation in protocol

Risk Category: Clinical Care & Patient Safety

GUIDELINE

This Guideline does not replace the need for the application of clinical judgment in respect to each individual patient.

1. INTENDED OUTCOMES:

- Clinical staff will be able to interpret clinical findings of a neurovascular assessment and act appropriately
- Neurovascular assessments will be completed and effective
- Babies, children and young people will benefit clinically from thorough neurovascular assessments
- The incidence of neurovascular related complications will be reduced

2. BACKGROUND INFORMATION

Surgery, disease and injuries have the potential to cause nerve and vessel damage to children’s extremities. To decrease the risk of permanent damage to an extremity, neurovascular assessments must be performed. Identifying and treating an extremity at risk before damage occurs, is essential.

Aim

This clinical procedure will provide clinicians with the correct procedure for performing an effective neurovascular assessment. It will provide examples of complications and strategies for managing potential complications. It will enable the clinician to undertake and satisfactorily complete a competent neurovascular assessment.

Assessment

This clinical document is suitable for children and young people 0-18 years with the potential to develop neurovascular complications. This document is a clinical procedure. For a more comprehensive understanding of neurovascular assessment, the self-directed learning package should be completed. This is available on the Kaleidoscope website.

The word extremity is used throughout this document and refers to any part of a child’s limb, including digits.
3. PRIOR TO THE ASSESSMENT

Inform the patient and parent what you are going to do, why you are going to do it and gain consent.

Staff Preparation
To complete a neurovascular assessment, the clinician will require a HNELHD Neurovascular Assessment Chart 77420 – Mar03. Prior to touching the patient, it is mandatory for staff follow relevant: "Five moments of hand hygiene", infection control and documentation practices.

Place patient sticker on chart and indicate on the SPOC chart that the neurovascular chart is in use. Fill out details such as hospital, the extremity to be assessed and the type of immobilisation. This could include:

- Hamilton-Russell traction
- Gallows traction
- Back-slab
- Plaster cast
- Splint
- Collar & cuff

Put in the frequency of assessment based on the recommendations according to risk in this guideline in the next section.
4. RECOMMENDED FREQUENCY OF NEUROVASCULAR ASSESSMENT ACCORDING TO RISK

There are three levels of risk.

**High Risk**
The extremity is obviously compromised or likely to become compromised

$\frac{15}{60}$ neurovascular assessments are undertaken until the risk has decreased or definitive treatment has commenced.

The risks include:
- Identified or suspected compartment syndrome
- A dislocated joint
- Known or suspected crush injury
- Severe swelling
- Ischaemia
- Vascular stasis
- Absent pulse where one was previously present
- Pain that cannot be controlled with opioid analgesia
- Extensive surgery to repair the extremity (which may involve replantation)
- Extensive soft tissue injury
- MO orders

**Moderate Risk**
The extremity is at risk of compromise or within 24 Hours of a procedure or injury, or the patient is within 24 hours of admission

$\frac{1}{24}$ neurovascular assessments are undertaken until the risk has decreased or 24 hours has elapsed.

Risks include:
- A new device on the extremity, such as a cast or splint
- Where a dislocated joint has been relocated
- A change to complex dressings and bandages (such as negative pressure)
- Mild or moderate swelling
- Post-surgery
- A child who cannot communicate effectively
- Change of traction
- Change of traction weight

**Low Risk**
The Extremity is at Lower Risk of Neurovascular Compromise

$\frac{2}{24}$ assessments until discharge from hospital or there is a change in the condition of the extremity.
5. CLINICAL ASSESSMENT OF THE EXTREMITY USING DEFINED PARAMETERS

The patient’s neurovascular status must be monitored and reassessed regularly to show a pattern of deterioration or improvement. Acceptable parameters are defined to avoid inconsistency and confusion in clinical care. All clinically significant abnormal clinical findings must be documented on the Neurovascular Assessment Chart and a clinical review must be instigated and completed.

Clinical Assessment

Assessing the colour of the extremity

The colour of extremity should be compared to the non-affected extremity where possible.

An extremity with vascular impairment may be:
- Pale
- Mottled
- Dusky
- Red (inflammation)

Be aware of other conditions that can cause abnormal colouration of the skin, examples include:
- Shock
- Low haemoglobin
- Bruising
- Jaundice
- Birthmarks
- Medication (steroids)
- Endocrine disorders
- Pigment disorders
- Pain disorders
- Haematologic disorders
Assessing the temperature of the extremity

Good circulation and perfusion of blood into an extremity is indicated by warm tissue. Skin should feel warm to touch without feeling hot or cold; compare to the unaffected extremity where possible.

A cold extremity may be an indication of poor blood flow to the extremity, or that the child is cold. Keep an open mind about other possible causes, such as shock. Extremities should be the same temperature. A unilateral cold limb should be investigated as a matter of urgency.

A hot extremity or an extremity with hot areas may be an indication of poor venous return, venous congestion, inflammation or infection.
Assessing Capillary Refill

Capillary refill is the time taken for blood to return to a part of an extremity such as a finger or toe after it has been pressed to cause blanching. Press the soft pad of the finger or toe until it turns white and count the time needed for the colour to return.

Satisfactory circulation and perfusion of an extremity is indicated by a capillary refill time of less than 3 seconds. A sluggish or absent refill time could indicate a blood supply issue. A fast refill time could indicate a venous return issue.
Assessing the presence of a pulse

A pulse should be assessed distally to the injured part of the extremity or cast; with the purpose of assessing arterial flow.

Write on the chart the name of the pulse that is being assessed.

Adequate arterial circulation is indicated by the presence of a pulse. The pulse is assessed as weak, strong or absent.

If there is uncertainty about whether a pulse is present, ask a senior staff member or the Team Leader to check the pulse.

When a pulse is absent due to neurovascular impairment, an urgent clinical review must be instigated and completed within 30 minutes.
Assessment of swelling to an extremity

Compare the swollen extremity to the non-swollen extremity if possible.

Measure the circumference of the limb with a tape measure and record it – mark the area measured, for consistency.

Extra attention must be given to an extremity at risk of swelling that is covered in bandages or medical therapy devices.

Patients returning from theatre after fracture reduction surgery who have a full Plaster of Paris cast are at high risk of neurovascular complications.

Ensure a limb at risk of swelling, or that is swollen is elevated above the level of the patient’s heart. Ensure the method of elevation is effective and safe.

Name the body part affected and whether it is swollen - yes or no.
Assessment of sensation

Nerve conduction is assessed by the presence of sensation by lightly touching the extremity. A number of nerves supply sensation to an extremity; relevant areas should be assessed referring to the Neurovascular Assessment Chart.

Abnormal nerve function is indicated by an alteration in sensation around the injured area. This should be compared to the same unaffected area on another extremity where possible.

The clinician should touch the area of the skin lightly both proximally and distally to the affected area. The patient should be asked (where developmentally appropriate) to communicate any changes to parents and clinical staff. Age appropriate techniques should be implemented. Using methods such as feathers, ice or playing a game may be helpful in achieving a meaningful response.

It is not possible to assess sensation for a child who cannot communicate effectively or is not co-operative. This should be recorded appropriately.

Alterations in sensation can include:
- Numbness
- Tingling
- Pins & needles
- Burning
- Allodynia (pain response is triggered by a stimulus that does not normally produce pain)

Documentation should include where the patient describes the alteration of sensation and which nerve is affected.

Children with a nerve block or an epidural have an intentional alteration in sensation to block noxious sensations. Neurovascular assessment must be attended in conjunction with these medical interventions, without ignoring the risk of neurovascular compromise. It is the professional responsibility of staff to have adequate knowledge and competency to care for children treated with nerve blocks and epidurals.

Version 1  May 2016 Page 12
Assessment of movement and range of motion

Movement and range of motion can be assessed by asking the child to move their extremity (distal to the injury). This can be encouraged by tickling or playing games.

A lack of movement can be an indication of swelling, injury, pain or nerve damage.

Range of motion can be assessed by moving the patient’s extremity passively.

Range of motion should be compared in both extremities where practicable. Do not force a joint to move, or repeat this part of the assessment if it causes pain.

Some pain on movement is typical after surgery or injury, and should be treated. Pain at rest must be investigated, especially if analgesia has been administered or traction is in place.

Name the body part and describe the type of movement assessed. It can be active, passive or nil. With or without pain.
Assessment of pain

Pain is one of the earliest and most significant symptoms of an extremity with neurovascular compromise. It is an indication of soft tissue compression and/or injury.

Effective relief of pain is a requirement for the psychological welfare of children. Crying is not the only sign of pain in a child. Extreme pain will lead to abnormal physiological mechanisms such as:
- Increased respiratory rate
- Increased pulse rate
- Sweating
- Grimacing

Look and listen. Look at the child. Listen to the parents.

Follow the Paediatric Pain Management Guideline and use a Paediatric Pain Assessment Tool.

6. COMPARTMENT SYNDROME

Muscle groups are enclosed within a thin film of tissue called fascia, which forms its own segment or compartment. It is non-elastic and will constrict oversized contents (swollen muscles).

If muscle tissue begins to swell, the compartment becomes confined and the muscle cells become poorly perfused and hypoxic, leading to ischaemia. Dying cells produce toxins that cause pain. Movement becomes extremely painful and strong analgesia may be ineffective. Pain on passive movement will be intolerable.

Pain from a developing compartment syndrome will present as:
- Non-localised
- Persistent
- Progressive
- Unrelieved by strong opioid analgesia
- Exacerbated by muscle stretching on passive movement

This pain is often mistaken for poorly controlled pre-operative or post-operative pain (a complication in its own right). Attention must focus on the location and characteristics of pain. Any doubt about the cause of uncontrolled pain must be clinically reviewed within 30 minutes, as per DETECT protocol. If pain is not relieved after clinical review and intervention by a junior medical officer, a senior medical officer, such as a registrar, fellow, staff specialist or consultant should be consulted.

Guidelines for the general management of paediatric pain are available on the Kaleidoscope website.

A child’s extremity with a compartment syndrome must be treated within 4 hours to avoid permanent damage.
## Paediatric Orthopaedic Neurovascular Assessment

7. **FLOWCHART**

[Flowchart image showing the assessment process for children at risk of neurovascular compromise, including checks for Colour, Temperature, Pulse, Capillary refill, Swelling, Sensation, Range of Motion, Pain, and a decision on whether the child has a possible compartment syndrome.]
8. IMPLEMENTATION AND MONITORING COMPLIANCE

The owners/developers of the document must:

1. The guideline will be placed on the HNE guideline website.
2. A copy of the guideline will be sent to all the relevant stakeholders.
3. The nursing staff on the wards will be given an in-service regarding the updated guideline, including the changes within a month of ratification.
4. The nursing educators will be directed toward the updated guideline and the learning package.
5. A basic draft clinical audit tool is available at Appendix One.
6. Compliance will be monitored with annual audits and an associated action plan, where required, and will be sent to the JHCH Clinical Quality and Patient Care Committee.

9. APPENDICES

HNELHD Neurovascular Assessment Chart 77420 – Mar03.
