F	T			
Alert	nder New South Wales Clinical Excellence Commission.			
	Different brands of insulin are not bioequivalent. Do not substitute between brands.[13]			
	Actrapid is the ANMF group's recommended short-acting insulin for IV infusion in neonates.			
	International units are hereafter referred to as "units".			
	High risk of hypoglycaemia.			
	Insulin binds to the plastic of giving sets. Flush the plastic tubing with 20 mL of prepared insulin solution			
	into a receptacle prior to connecting to the infar	_		
La di a di a a		liably delivered even after preconditioning and flushing.		
Indication	Treatment of persistent hyperglycaemia.			
Action	[For treatment of hyperkalaemia, see Insulin – hyperkalaemia].			
Action	Insulin is a polypeptide hormone that acts on cells throughout the body to stimulate uptake, utilisation storage of glucose resulting in a lowering of blood glucose. Insulin stimulates the liver to store glucose in			
	form of glycogen and facilitates the entry of glucose into muscle and adipose tissue. It inhibits lipolyst proteolysis and gluconeogenesis, enhances protein synthesis and conversion of excess glucose into fat.			
Drug type	Polypeptide hormone – lowers blood glucose.			
Trade name	Actrapid [Novo Nordisk]			
Presentation	100 units/mL in a 10 mL vial and 3 mL Penfill.			
Dose	Treatment of hyperglycaemia:			
Dose	Intravenous:			
	Starting dose: 0.05 unit/kg/hour.			
	Dose range: 0.01 to 0.1 unit/kg/hour. Titrate in small increments to blood glucose: Target blood glucose level (BGL) 8 to 10 mmol/L [1, 2].			
Dose adjustment				
	euglycemia [3].			
	ECMO: Data limited in pre term neonates to mal	ke recommendation.		
	Renal impairment: Limited data in neonates. Lov	ver doses may be required in severe renal failure.		
	Hepatic impairment: Limited data in neonates. C	close monitoring of BGL advised due to lability of BGL [4].		
Maximum dose

Monitoring	Blood glucose level (BGL)	
	After Initiation of infusion: 30 minutes - 2 hours based on the infant's risk profile until stabilised.	
	On maintenance: 4–6 hourly.	
	After cessation of infusion: At 1 hour.	
	Alteration of infusion: Within 1 hour.	
	Serum potassium concentration.	
Contraindications	Hypersensitivity to regular insulin or any of its components.	
	During episodes of hypoglycaemia.	
Precautions	Hypoglycaemia is a common adverse effect. Blood glucose must be monitored closely to detect	
	hypoglycaemia.	
	Do not adjust the rate of the maintenance solution or other infusions when insulin is commenced or the	
	insulin infusion rate is altered. For example, if insulin is commenced or the rate of the insulin infusion is	
	increased, do not turn down the maintenance solution to compensate for the total volume delivered. The	
	amount of glucose being delivered to the infant will then be reduced as the insulin is commenced or dose	
	is increased, possibly causing hypoglycaemia in an already unstable infant.	
	If ceasing insulin or changing the strength, be careful to remove and replace the previous line and T-piece	
	to avoid flushing through insulin remaining in the tubing.	
	Administer IV bolus medication via separate IV access to avoid insulin bolus administration.	
Drug interactions	The following may reduce insulin requirements: Octreotide, beta-adrenergic blocking agents, angiotensin	
	converting enzyme inhibitors, salicylates, anabolic steroids, alpha-adrenergic blocking agents, quinine,	
	quinidine and sulfonamides.	
	The following may increase insulin requirements: Thiazides, furosemide, ethacrynic acid, glucocorticoids,	
	thyroid hormones, sympathomimetics, octreotide, growth hormone, and diazoxide.	
	Beta blocking agents may mask the symptoms of hypoglycaemia and delay recovery from hypoglycaemia.	
	Hypoglycaemia in the presence of concomitant use of a beta-adrenergic blocking agent may precipitate a	
A.I	hypertensive crisis.	
Adverse reactions	Hypoglycaemia; hypokalaemia; and hyponatraemia.	
	Urticaria and anaphylaxis (extremely rare). Insulin resistance may develop resulting in a larger dose requirement.	
Compatibility	Fluids: glucose 5%, glucose 10%, glucose 50%, sodium chloride 0.9%.	
Compatibility	Tridias. glucose 370, glucose 1070, glucose 3070, sodium emoride 0.370.	
	Y-site:[12,13] Aciclovir, aminophylline, amphoteiricin B lipid complex, atenolol, atropine, azathioprine,	
	aztreonam, calcium chloride, calcium gluconate, caspofungin, cefazolin, cefepime, cefotaxime,	
	ceftazidime, ceftriaxone, cefuroxime, chloramphenicol, clindamycin, cloxacillin, dexamethasone,	
	enalaprilat, epoetin alfa, erythromycin lactobionate, fentanyl, fluconazole, folic acid, fosphenytoin,	
	ganciclovir, hydrocortisone, ibuprofen, imipenem-cilastatin, indomethacin, lidocaine , linezolid,	
	magnesium sulfate, Meropenem, methadone, methylprednisolone, metoclopramide, metoprolol,	
	metronidazole, milrinone, naloxone, nitroglycerin, nitroprusside, octreotide, pamidronate, pancuronium,	
	penicillin G, pentobarbital, pentoxifylline, phenobarbital, potassium acetate, potassium chloride, propofol,	
	pyridoxine, remifentanil, sodium bicarbonate, streptokinase, thiamine, ticarcillin –clavulanate, urokinase,	
	vancomycin, vecuronium, verapamil, vitamin B complex with C.	
	Variable compatibility:[12] amikacin, amiodarone, amphotericin B conventional, ampicillin, cyclosporine,	
	digoxin, dobutamine, dopamine, epinephrine, furosemide, gentamicin, heparin, hydralazine, midazolam,	
	morphine sulfate, multiple vitamin injection, norepinephrine, ondansetron, pantoprazole, tobramycin,	
	vasopressin.	
Incompatibility	Y-site administration:[12,13] Cefoxitin, diazepam, diazoxide, glycopyrrolate, ketamine, labetalol,	
	phenytoin, piperacillin -tazobactam, propranolol, protamine, rocuronium, sulfamethoxazole-trimethoprim	
Stability	Actrapid: Prepared solutions are stable at room temperature (< 25°C) for 24 hours. (extrapolated from	
	Insulin Human Regular) [12]	
Storage	Store human insulin between 2 and 8°C. Do not freeze.	
	Protect from excessive heat and light. Should appear clear and colourless.	
Excipients	Glycerol, metacresol, zinc chloride, water for injections. Hydrochloric acid and sodium hydroxide are used	
	to adjust the pH. Contains less than 1 mmol sodium (23 mg) per dose, i.e. is essentially 'sodium-free'.

Special comments	Insulin is adsorbed to the plastic of intravenous bags, syringes, and tubing which reduces the delivery of insulin [5-7].	
	Twenty mL of insulin priming solution at concentrations of 0.1 unit/mL and 0.05 unit/mL were found to	
	deliver 80% and 26.5% of the expected insulin. Insulin concentrations ≤ 0.05 unit/mL are not reliably	
	delivered even after preconditioning and flushing [5, 6].	
Evidence	Efficacy	
	Treatment of hyperglycaemia in very low birth weight infants: Systematic review [2] of trials of	
	insulin infusion for treatment of neonatal hyperglycaemia found that use of an insulin infusion	
	obviates the need to decrease the concentration of glucose prescribed and optimised the	
	utilisation of calories by the infant resulting in significant increases in non-protein energy intake,	
	glucose intake and short-term weight gain. However, insulin infusion had no significant effect on	
	death, severe intraventricular haemorrhage, retinopathy of prematurity, bacterial sepsis, fungal	
	sepsis or necrotising enterocolitis; effects on other major morbidities were not assessed. These	
	trials did not report an excess of hypoglycaemia, possibly due to the more liberal target BSLs:	
	Collins 1991 [8] 4.4–9.9 mmol/L and Meetze 1998 [9] 5.5–9.9 mmol/L. Conclusion: Evidence	
	from randomised trials in hyperglycaemic VLBW neonates is insufficient to determine the effects	
	of treatment on death or major morbidities. [2] [LOE I GOR D]	
	Prevention of neonatal hyperglycaemia in very low birth weight infants: Systematic review [10]	
	of trials of early insulin infusion for prevention of neonatal hyperglycaemia found that use of an	
	insulin infusion reduced hyperglycaemia but increased death before 28 days and increased the	
	risk of hypoglycaemia. The reduction in hyperglycaemia was not accompanied by significant	
	effects on major morbidities; effects on neurodevelopment are awaited. The evidence does not	
	support the routine use of insulin infusions to prevent hyperglycaemia in VLBW neonates. [10][LOE I GOR	
	B]	
	Tight glycaemic control with insulin in hyperglycaemic very low birth weight infants: RCT in	
	infants born at < 30 weeks' gestation or < 1500 g with hyperglycaemia (2 consecutive BGL > 8.5	
	mmol/L 4 hours apart) randomly assigned to tight glycaemic control with insulin (target BGL 4–6	
	mmol/L) or restrictive guidelines for starting insulin (target BGL 8–10 mmol/L). Infants in the	
	tight group had a lesser lower leg growth rate (P < 0.05), but greater head circumference growth	
	(P < 0.0005) and greater weight gain $(P < 0.001)$ to 36 weeks' postmenstrual age than control	
	infants. Tight group infants had lower daily BGL and greater incidence of hypoglycaemia (BGL <	
	2.6 mmol/L) (25/43 vs 12/45; P < 0.01) than controls. There were no significant differences in	
	nutritional intake or in the incidences of mortality or morbidity. The balance of risks and benefits	
	of insulin treatment in hyperglycaemic pre-term neonates remains uncertain. [1] [LOE II GOR D]	
	Guidelines: ESPGHAN 2005 recommended the use of insulin should be restricted to conditions	
	where reasonable changes in glucose infusion rate do not control marked hyperglycaemia. [11]	
	Although this recommendation is now out of date, current evidence is consistent with this	
	recommendation. Pharmacokinetics	
	Following IV administration, the observed half-life of insulin ranges from 5 to 15 minutes.
